10. References and Bibliography ……. 38

Executive Summary

India stands at a critical juncture in the global artificial intelligence race. While the nation produces over 1.5 million engineering graduates annually and maintains one of the world's largest pools of science, technology, engineering, and mathematics (STEM) talent, a significant and widening gap exists between the skills these graduates possess and the demands of the AI-driven economy. This comprehensive research report examines the multifaceted limitations that Indian engineering students face in acquiring and demonstrating competency in artificial intelligence technologies.

The research reveals that only 15.1% of Indian engineering graduates are job-ready for AI and machine learning roles, despite 92% of students already utilizing AI tools in their studies. The employability crisis extends beyond technical skills, with 44.1% of graduates overall being deemed employable by industry standards. This report identifies several critical limitation categories: technical skill gaps in advanced mathematics and algorithms, deficiencies in soft skills and learning agility, outdated and misaligned curricula, inadequate infrastructure and resource access, and the persistent challenge of brain drain coupled with limited research and development opportunities.

Through comprehensive analysis of recent data from the Mercer-Mettl India Graduate Skill Index 2024, the Wheebox India Skills Report 2024, the Carnegie Endowment's research on India's AI puzzle, and academic studies on engineering education reform, this report synthesizes evidence-based findings and provides strategic recommendations for stakeholders across academia, industry, and policy domains. The report concludes that while the challenges are significant, they are not insurmountable, provided there is a coordinated effort to modernize the educational ecosystem and align it with the rapid advancements in the global AI landscape.

Chapter 1: Introduction

1.1 The Global AI Revolution and the “AI Arms Race”

The world is experiencing an unprecedented transformation driven by artificial intelligence. The United States and China, recognized as the world’s two “AI superpowers,” are engaged in what observers describe as an “AI arms race,” with both nations investing heavily in AI research, infrastructure, and talent development. This global competition has created an environment where countries must rapidly develop AI capabilities or risk being relegated to observer status in the technological revolution of the 21st century.

The acceleration of AI development, particularly in generative models and large-scale neural networks, has shifted the paradigm of global economic and strategic power. Nations are no longer competing solely on industrial output or traditional software services; the new currency of global dominance is the ability to harness data, compute, and human intelligence to create autonomous systems. For a developing economy like India, the stakes are exceptionally high. The transition from a service oriented IT hub to an AI-driven innovation center is not merely an economic choice but a strategic necessity for national security and long-term prosperity.

1.2 India’s Strategic Position: The IndiaAI Mission and National AI Stack

India, with its large population of technically trained professionals and growing digital economy, has positioned itself as an emerging player in the global AI competition. The Indian government launched the National AI Mission (NAIM), also known as the IndiaAI Mission, in 2024 with an ambitious budget of Rs. 10,371.92 crore (approximately $1.25 billion) over five years. This mission encompasses seven elements of what researchers term the “AI stack”: computing and AI infrastructure, data, talent, research and development, capital, algorithms, and applications.

The IndiaAI Mission is designed to democratize access to AI resources, fostering an ecosystem where startups, researchers, and students can innovate without the prohibitive costs of high-performance computing. By focusing on “AI for All,” the government aims to leverage technology to solve uniquely Indian problems in sectors such as agriculture, healthcare, and education. However, the success of this mission depends heavily on the “talent” pillar of the stack. Without a workforce capable of utilizing these resources effectively, the infrastructure risks becoming an underutilized asset.

1.3 The Engineering Paradox: Scale vs. Quality in the Indian Context

India's engineering education system is characterized by remarkable scale and significant challenges. The country produces approximately 1.5 million engineering graduates annually, making it one of the world's largest producers of engineering talent. Yet this volume masks a quality crisis: according to industry surveys, 56% of engineering graduates are deemed unemployable by industry standards, and 95% of engineers express concern that artificial intelligence will displace their jobs.

This paradox—producing massive numbers of graduates while struggling with employability—reflects systemic issues in how engineering education is structured, delivered, and aligned with industry needs. The curriculum, faculty expertise, infrastructure, and pedagogical approaches that served India well in the software services era are increasingly inadequate for the AI-driven economy. The shift from deterministic programming to probabilistic machine learning requires a fundamental rethinking of the engineering mindset, moving from "following instructions" to "designing intelligent systems."

1.4 Research Objectives and Methodology

This technical report examines the specific limitations that Indian engineering students encounter when attempting to develop competency in artificial intelligence. The primary objectives of this research are to:

1. Identify the core technical and theoretical gaps in the current engineering curriculum that hinder AI readiness.
2. Analyze the socio-economic and infrastructural barriers that prevent students from accessing modern AI tools and compute resources.
3. Evaluate the effectiveness of current educational reforms and industry-academia partnerships in bridging the talent gap.
4. Provide a set of actionable recommendations for policy-makers, institutional leaders, and students to navigate the AI transition.

The methodology involves a synthesis of secondary data from authoritative sources, including the Mercer-Mettl India Graduate Skill Index, the Wheebox India Skills Report, and the Carnegie Endowment for International Peace. By cross-referencing industry

demand with academic output, the report provides a comprehensive assessment of the current state of AI readiness among Indian engineering students.

Chapter 2: The Indian AI Talent Landscape

2.1 Statistical Overview of Graduate Employability (2024-2026)

India's engineering education system operates at an enormous scale. With 1.5 million graduates produced annually, India represents a significant portion of the world's engineering talent supply. However, this scale masks critical quality concerns that directly impact AI readiness. According to the Wheebox India Skills Report 2024, employability among Indian engineering graduates has improved to 51.25% in 2024, up from 46.22% in 2023. While this represents progress, it also means that approximately 49% of graduates lack the foundational competencies required for employment.

The specific data regarding AI and machine learning roles is even more sobering. Only 15.1% of Indian graduates are job-ready for AI and ML positions, despite the growing demand for such talent. This represents a critical mismatch between supply and demand in the AI talent market. The following table summarizes the key employability metrics for Indian engineering graduates as of early 2026:

Metric	Value	Source
Annual Engineering Graduates (India)	1.5 Million	[4]
Overall Employability Rate (2024)	51.25%	[4]
AI/ML Job-Ready Graduates	15.1%	[5]
Overall Employable Graduates (Mercer-Mettl)	44.1%	[5]
Female Graduate Employability	52.8%	[4]
Tier-1 College Graduate Employability	66.0%	[5]

2.2 Tier-wise Performance Disparities: The Digital Divide in Education

A critical finding in the employability data is the significant variation in graduate quality based on institutional tier. Graduates from Tier-1 colleges (IITs, NITs, and equivalent institutions) demonstrate substantially higher employability rates compared to those from Tier-2 and Tier-3 institutions. Tier-1 college graduates achieve approximately 66.0% employability for both technical and non-technical roles, while the overall average across all tiers stands at 44.1%.

This 22-percentage point gap represents a significant quality differential when considering the absolute numbers involved. Given that the majority of India's 1.5 million annual engineering graduates attend Tier-2 and Tier-3 institutions, this creates a situation where the majority of the talent pool falls below the employability threshold. This "digital divide" in education is not just about prestige; it reflects a fundamental difference in access to experienced faculty, modern laboratories, and industry networking opportunities. For AI education, which requires specialized hardware and high-level theoretical instruction, this gap is even more pronounced.

2.3 The Demand-Supply Mismatch: Analyzing the Talent Gap

The demand for AI and machine learning professionals in India significantly exceeds the current supply of qualified talent. Research indicates a 60–70% gap between demand and supply for AI/ML and generative AI specialists. India's current AI workforce comprises approximately 4.20 lakh (420,000) professionals, but demand is projected to grow from 600,000–1,000,000 in 2024 to more than 2,000,000 by 2030. This growing gap creates both opportunity and risk. The opportunity lies in the potential for Indian graduates to secure high-value positions in the global AI economy. The risk is that without rapid upskilling and education reform, India will fail to capture these opportunities, and the gap will be filled by talent from other nations or by automation. Furthermore, the nature of the demand is shifting; industry is no longer looking for "coders" but for "problem solvers" who can architect AI solutions and understand the ethical and social implications of their work

.

2.4 Student Perspectives: AI Adoption vs. Professional Readiness

A striking finding from recent surveys is that 92% of students already use AI tools in their studies, with nearly one in four using AI daily. This widespread adoption of AI tools by students stands in sharp contrast to the relatively low percentage of graduates who are deemed job-ready for AI roles. This paradox suggests that while students are gaining familiarity with AI tools through informal usage (such as using LLMs for homework or basic coding assistance), they are not developing the deeper technical understanding, theoretical foundations, and problem-solving capabilities required for professional AI work.

This “surface-level adoption” can lead to a false sense of competence. Students may become proficient at prompting an AI to generate code but remain unable to debug that code, explain its underlying logic, or assess its computational complexity. To bridge this gap, the focus must shift from using AI as a “crutch” to using it as a “catalyst” for deeper learning and innovation.

Chapter 3: Technical Skill Gaps and Foundational Deficiencies

3.1 The Mathematics and Statistics Crisis

Moving Beyond Rote Learning One of the most fundamental limitations facing Indian engineering students is inadequate grounding in advanced mathematics and statistics—the theoretical foundations upon which artificial intelligence and machine learning are built. While engineering curricula typically include calculus, linear algebra, and basic statistics, the depth and application-oriented nature of these subjects often falls short of what is required for AI work. Machine learning algorithms depend critically on understanding concepts such as linear algebra (matrix operations, eigenvalues, singular value decomposition), multivariable calculus (gradients, Hessians, optimization), probability theory, and statistical inference. Many Indian engineering students complete their undergraduate education with only surface-level understanding of these topics, having learned them primarily for examination purposes rather than for practical application. This "rote learning" approach fails when students are faced with complex AI problems that require an intuitive grasp of mathematical principles.

3.2 Advanced Algorithm Design and Computational Complexity:

A second critical technical gap relates to algorithm design and computational complexity analysis. While many engineering curricula include a course on data structures and algorithms, the focus often remains on classical algorithms rather than the algorithmic techniques specific to machine learning and AI applications. Students frequently lack proficiency in dynamic programming and optimization techniques specific to machine learning, graph algorithms and their applications in neural networks, and complexity analysis for understanding the computational requirements of different AI approaches. This gap becomes particularly acute when students attempt to work with large datasets or implement complex models, where understanding computational complexity directly impacts the feasibility and efficiency of solutions. Without this knowledge, students may design systems that are theoretically sound but computationally impossible to train or deploy in a production environment.

3.3 Software Engineering Excellence:

Beyond Basic Coding While Indian engineering graduates often possess basic programming skills, they frequently lack the advanced software engineering practices necessary for professional AI

development. The gap extends beyond simple coding ability to include version control and collaborative development practices, testing and debugging methodologies for machine learning code, code documentation and maintainability standards, and performance optimization and profiling techniques. The Carnegie Endowment research notes that many engineering graduates will likely be unable to compete with AI for basic coding tasks, suggesting that without deeper technical expertise, entry-level programming positions themselves are becoming vulnerable to automation. This creates pressure for graduates to develop more sophisticated technical capabilities, yet the current educational system often does not provide adequate preparation. Professional AI development is a team-based, iterative process that requires a level of software engineering discipline that is rarely taught in undergraduate programs.

A significant gap exists in the domain-specific knowledge of engineering graduates, particularly in key AI subfields like Natural Language Processing (NLP), Computer Vision, and Reinforcement Learning. While leading Tier-1 institutions are beginning to introduce specialized courses in these areas, such offerings are not widespread across the broader engineering education landscape. Consequently, many students complete their studies without formal exposure to these vital domains, diminishing their competitiveness in the job market.

The table below summarizes the critical technical skill mismatches observed among Indian engineering graduates:

Technical Skill Area	Identified Gap in Education	Industry Requirement
Mathematics	Superficial exposure to calculus and algebra	A deep grasp of optimization and probability theory
Algorithms	Overemphasis on traditional sorting and searching methods	Proficiency in ML-specific optimization and graph algorithms
Software Engineering	Focus on basic coding and syntax	Advanced skills in version control, CI/CD, and model deployment
AI Specialization	Minimal or no exposure to NLP and Computer Vision	Hands-on experience with contemporary neural network architectures
Data Engineering	Weak foundational understanding of data pipelines	The ability to effectively manage large-scale, complex, real-world datasets

---

Chapter 4: Soft Skills and Learning Agility in the AI Era

4.1 The “Human-in-the-Loop”: Why Soft Skills Matter More Than Ever

The transition from traditional software development to AI-driven systems has fundamentally changed the nature of required professional skills. While technical expertise remains essential, the ability to think critically, communicate complex ideas, collaborate across disciplines, and continuously learn has become equally important— if not more so—in the AI economy. The Mercer-Mettl India Graduate Skill Index 2024 identifies soft skills as increasingly critical for success in the AI workplace. Employers report that they are “increasingly focusing on graduates who possess soft skills like critical thinking, communication skills and learning agility.”

This represents a significant shift from the traditional emphasis on pure technical competence. In an era where AI can generate code and perform routine data analysis, the human role is increasingly focused on high-level decision-making, ethical oversight, and strategic alignment. These tasks require a level of emotional intelligence and critical reasoning that machines cannot yet replicate.

4.2 The Learning Agility Paradox: Adapting to Rapid Technological Shifts

One of the most striking findings in recent employability research is the learning agility paradox. Indian graduates demonstrate an employability of 48% in learning agility, compared to 54% in overall soft skills. Learning agility—the ability to quickly acquire new knowledge and adapt to changing circumstances—is particularly critical in AI, where the field evolves rapidly and professionals must continuously update their skills.

The relatively low learning agility scores suggest that many Indian engineering students are trained to master fixed curricula but struggle when confronted with novel problems or rapidly changing technological landscapes. This limitation becomes particularly problematic in AI, where practitioners must regularly learn new frameworks, algorithms, and best practices. The “exam-oriented” nature of Indian education, while effective for memorization, often discourages the intellectual curiosity and flexibility required for lifelong learning.

4.3 Critical Thinking and Open-Ended Problem Solving

Engineering education traditionally emphasizes problem-solving within well-defined domains with clear right and wrong answers. However, AI development frequently involves ambiguous problems with multiple possible solutions, trade-offs between competing objectives, and the need to make decisions with incomplete information. Many Indian engineering students lack experience with open-ended problem formulation and scoping, systems thinking and understanding complex interdependencies, and ethical reasoning about AI implications and societal impact.

These capabilities are often developed through experience rather than formal instruction, yet the traditional engineering education model provides limited opportunities for such experiential learning. To develop these skills, students must be encouraged to work on real-world projects that do not have “back-of-the-book” answers.

4.4 Communication, Collaboration, and Cross Functional Leadership

The AI industry increasingly requires professionals who can communicate technical concepts to non-technical stakeholders, collaborate across functional areas (business, design, operations), and work in diverse, often distributed teams. Many Indian engineering students, particularly those from non-English medium backgrounds, struggle with technical writing and documentation, presentation skills and public speaking, and cross-functional collaboration.

The traditional engineering education model, with its emphasis on individual problem-solving and examination-based assessment, provides limited opportunities for students to develop these collaborative skills. In a professional AI project, a data scientist must be able to explain the “why” behind a model’s prediction to a business manager or a policy-maker. Without these communication skills, even the most technically brilliant engineer will struggle to make an impact.’

Chapter 5: Educational Infrastructure and Curriculum Constraints

5.1 The Curriculum Lag: Modernizing Outdated Syllabus Frameworks

One of the most frequently cited limitations in Indian engineering education is the lag between curriculum content and industry needs. While the All India Council for Technical Education (AICTE) has recently moved to integrate AI into engineering curricula as a core subject rather than an elective, significant implementation challenges remain. A critical observation from industry practitioners is that many colleges have AI in their curriculum, but “it’s 10 years outdated.”

This suggests that while institutions have nominally incorporated AI content, the specific topics, tools, and approaches taught often reflect earlier generations of AI technology rather than current best practices. For example, a student might be taught the basics of expert systems or simple decision trees while the industry has moved on to large language models and multi-modal neural networks. Bridging this gap requires a more dynamic and responsive curriculum design process.

5.2 AICTE Initiatives and the Challenge of National Implementation

Recognizing the urgency of curriculum reform, AICTE has undertaken several initiatives, including making AI a mandatory core component of engineering curricula as of 2024-2025. The goal is to integrate AI across all engineering disciplines by 2026, including topics on data privacy, algorithmic bias, transparency, and responsible usage. However, these policy-level changes face significant implementation challenges. The integration of AI across all engineering disciplines requires not just curriculum revision but also faculty retraining, infrastructure investment, and assessment methodology changes.
The following table summarizes the key AICTE initiatives and their current status:

Initiative	Objective	Current Status (2026)
AI as Core Subject	Make AI mandatory for all engineering students	Fully implemented across all recognized institutions

Integrated AI Framework	Embed AI concepts into civil, mechanical, and electrical engineering	In progress; varying levels of adoption across tiers
Responsible AI Module	Teach ethics, bias, and transparency in AI systems	Mandatory module in final-year project work
Teacher Training (FDP)	Upskill faculty in modern AI tools and techniques	Over 60% of faculty trained; ongoing regional workshops

5.3 Faculty AI Literacy: The “Train the Trainer” Bottleneck

A critical bottleneck in curriculum reform is the limited AI literacy among engineering faculty. Many faculty members, particularly in Tier-2 and Tier-3 institutions, received their own training in an era before AI became a dominant technology. While some institutions have launched faculty development programs—such as IIT Kanpur’s Digital Literacy, Computational Thinking, Coding & AI (DLCCAI) Science Teacher Training Program—these efforts have not yet reached the majority of engineering educators.

The challenge is multifaceted: many faculty lack a deep understanding of modern AI techniques, have limited hands-on experience with current AI frameworks and tools, and struggle to redesign their courses to incorporate AI concepts effectively. Without a significant investment in “training the trainers,” any curriculum reform will remain a superficial change on paper.

5.4 Transitioning from Theory-Focused to Application Oriented Pedagogy

Traditional Indian engineering education emphasizes theoretical understanding and examination-based assessment. While theoretical foundations are important, the AI industry increasingly demands practical, application-oriented skills. Curricula have historically “focused on theory rather than application” and lack “integration of emerging technologies.”

This creates a mismatch where students graduate with theoretical knowledge but limited practical experience in building end-to-end AI systems from data collection to deployment, working with real-world, messy datasets, or implementing AI solutions within organizational constraints. To address this, institutions must adopt project based learning models where students are encouraged to build, test, and iterate on actual AI applications throughout their degree program.

Chapter 6: Infrastructure and Resource Accessibility

6.1 The Compute Crisis

GPU Access and High-Performance Computing Artificial intelligence, particularly deep learning, is computationally intensive. Training modern neural networks requires access to graphics processing units (GPUs) or specialized AI accelerators. However, access to such infrastructure remains limited for many Indian engineering students and institutions. While the Indian government has made significant progress in expanding AI compute infrastructure through the IndiaAI Mission, the distribution remains uneven. The IndiaAI Compute Portal currently offers shared, cloud-based access to 10,000 GPUs and 1,000 TPUs at subsidized rates. However, this represents a significant expansion from the initial target of 10,000 GPUs, reflecting the recognition of the critical shortage. The challenge for engineering students is that while this infrastructure exists at the national level, access at the institutional level remains limited. Many colleges lack dedicated GPU computing labs for student use, cloud credits or subsidized access to commercial AI platforms, and technical support for infrastructure management.

6.2 Software Ecosystems: Licensing, Tools, and Cloud Platforms

Access to professional-grade software is a significant hurdle for students, even beyond hardware limitations. Although essential open-source AI tools like TensorFlow, PyTorch, and scikit-learn are readily available, many specialized tools and platforms necessitate paid licenses or subscriptions. This includes commercial cloud platforms crucial for AI development (AWS, Google Cloud, Azure), specialized software for niche AI fields (e.g., computer vision, NLP), and advanced data visualization/analysis tools. While students can often utilize free or educational versions, these frequently come with limitations (reduced compute, storage, or feature restrictions) that ultimately hamper the full scope of their learning. As a result, the enterprise-level tools common in professional AI development remain largely inaccessible to the average student.

6.3 Regional Disparities: Connectivity and the Urban-Rural Divide

A pronounced infrastructure gap, particularly between Tier-1 and Tier-2/3 institutions, fuels a significant digital divide. Tier-1 institutions (like IITs and NITs) typically benefit from state-of-the-art computing labs, institutional subscriptions to commercial platforms, and faculty expertise in managing this infrastructure. Conversely, many Tier-2 and Tier-3 institutions struggle with inadequate computing hardware for AI projects, a lack of institutional support for necessary software licensing, and limited faculty knowledge in infrastructure management. This disparity directly compromises the quality of practical education and experience for students, thus widening the employability gap among graduates from different institutional tiers. Furthermore, despite overall improvements in internet penetration across India, bandwidth remains a critical challenge, especially in smaller cities and rural regions. Given that AI work involves massive dataset downloads (often gigabytes to terabytes), stable high-speed connections for cloud computing, and real-time collaboration on distributed systems, poor connectivity severely restricts the scope of student

Projects.

Chapter 7: The R&D Ecosystem and Systemic Challenges

7.1 The Brain Drain Phenomenon: Retaining Top-Tier AI Talent

One of the most significant limitations facing India's AI ecosystem is the migration of top-tier research talent to the United States and Europe. While India produces talented engineers at the undergraduate level (particularly from IITs), many of the most capable individuals pursue graduate studies abroad and subsequently establish their careers in Western countries. The Carnegie Endowment research notes that "top-tier AI talent being trained in India until the undergraduate level, presumably at institutions such as the Indian Institutes of Technology (IITs), ends up working in the United States or Europe after completing their graduate work."

However, there is some positive progress: the MacroPolo Global AI Talent Tracker's 2024 update suggests that India's ability to retain top-tier AI talent has improved. In 2020, nearly all Indian AI researchers pursued opportunities outside India, but by 2024, approximately 20% chose to remain in India. This indicates that retention of top-tier talent, while difficult, is achievable with appropriate incentives and infrastructure.

7.2 Innovation Metrics: The Publication-Patent Gap in Indian Research

India demonstrates a paradox in its research output: while the country shows impressive growth in AI-related research publications (particularly since 2010), it significantly lags behind the US and China in patents granted. This gap between publications and patents suggests a disconnect between theoretical research and practical innovation.

This limitation has direct implications for engineering students, as it indicates that research opportunities in India are more limited than in countries with stronger patent ecosystems, commercialization of research is less developed, and industry-academia collaboration on research is less mature. The incentive structures in many Indian institutions favor publication over practical innovation, which discourages students from developing products or startups based on their research.

7.3 Data Scarcity: The Need for India-Specific Datasets

A critical constraint on AI development in India is the limited availability of large volumes of high-quality, India-specific data for training AI models. The Carnegie Endowment research identifies this as a major gap: “Indian start-ups and researchers do not have access to the massive volumes of data that Google, Meta, Microsoft, and others have access to by virtue of being Big Tech firms with consumer- and business facing global platforms.”

This creates several limitations for engineering students: training datasets often focus on Western contexts and may not generalize well to Indian use cases, multilingual data in Indian languages remains limited compared to English, and domain-specific data for Indian applications (agriculture, healthcare, finance in Indian context) is sparse. Access to proprietary data from Indian firms is also limited due to data silos and privacy concerns.

7.4 Building Centers of Excellence: Public-Private Partnerships

While India has institutions like the IITs that conduct research, the number of institutions with strong AI research programs remains limited. This constrains opportunities for engineering students to engage in cutting-edge research during their studies. The Carnegie Endowment recommends that “India needs to identify at least twenty-five to thirty universities that will train the next generation of top-tier AI talent” and “focus on investing deeply in four to six centers of excellence in AI research through a combination of public and private sector sources.”

The following table outlines the current research landscape and the required shift for 2026 and beyond:

Research Metric	Current State (2024-2025)	Desired State (2026-2030)
Research Output	High publication volume, low patents	High publication volume with strong patenting
Talent Retention	~20% of top-tier researchers stay	>40% of top-tier researchers stay in India
Data Access	Reliance on Western open source data	Robust India-specific data ecosystems
Institutional Depth	5-10 world-class AI centers	25-30 centers of excellence across the country

Industry R&D	Limited industry-academia research	Deep, product-focused R&D partnerships

Chapter 8: Socio-Economic Influences and Future Outlook

8.1 Financial Barriers to Advanced AI Training

While basic engineering education is relatively affordable in India, advanced AI training and certifications often require significant financial investment. This creates barriers for students from economically disadvantaged backgrounds. Online AI courses and certifications (Coursera, Udacity, etc.) require paid subscriptions, specialized software and tools may require paid licenses, and GPU computing on cloud platforms requires payment.

The 25% of engineers who cite “lack of time due to work demands” and 20% who highlight “financial barriers to accessing upskilling” as obstacles to professional development indicate the magnitude of this challenge. Without financial support or subsidized access to high-quality training, the AI talent gap will likely widen along socio-economic lines.

8.2 Cultural Factors: Risk Aversion and Career Trajectories

Indian engineering culture, influenced by broader societal factors, tends toward risk aversion in career choices. Students and parents often prefer “safe” career paths (government jobs, established IT companies) over riskier but potentially more rewarding opportunities in AI research, startups, or entrepreneurship. This risk aversion manifests in limited participation in research and innovation activities, preference for established companies over startups, and avoidance of emerging technologies perceived as uncertain.

This cultural factor constrains the development of a vibrant AI innovation ecosystem and limits students’ exposure to cutting-edge AI work. To change this, the engineering ecosystem must celebrate and support entrepreneurial ventures and research oriented careers, providing a safety net for those who choose to innovate.

8.3 The “Jobpocalypse” Anxiety: Managing AI-Induced Displacement

A significant concern among engineering students is the potential for AI to displace human workers.

Surveys show that 95% of engineers worry that AI will take their jobs. This concern, while understandable, can paradoxically reduce motivation to develop AI skills, creating a self-fulfilling prophecy where students avoid AI because they fear it will eliminate their career prospects.

This psychological barrier is particularly acute for entry-level positions, where AI is increasingly being used for tasks such as code generation and data cleaning. To address this, students must be taught that AI is a tool for augmentation rather than just displacement. Those who learn to work with AI will be far more employable than those who ignore it.

progress is possible. The path forward requires coordinated action across multiple stakeholders: government, educational institutions, industry, and students themselves. The stakes are high. India’s ability to compete in the global AI economy depends critically on developing a workforce that can not only use AI tools but can innovate, research, and lead in AI development. By addressing the limitations identified in this report through strategic, coordinated action, India can transform its engineering education system and position itself as a global leader in artificial intelligenceAchieving progress necessitates coordinated efforts from various stakeholders: government, educational bodies, industry, and students. The future of India's role in the global AI economy is at stake, critically dependent on cultivating a workforce that is not only proficient in utilizing AI tools but can also drive innovation, research, and leadership in AI development. Through strategic and collaborative action to overcome the limitations outlined in this report, India has the potential to revolutionize its engineering education system and secure its position as a global leader in artificial intelligence.

Chapter 9: Strategic Recommendations and Conclusion

9.1 Recommendations for Policy and Regulation

India's government and regulatory bodies must enact policies to cultivate and retain elite AI talent. This includes offering competitive salaries to attract top AI researchers and faculty, utilizing mechanisms like the G20 talent visa (announced in December 2024) to draw in global experts, and providing dedicated research funding for promising startups and individual researchers.

Systematic investment in the development of faculty expertise is crucial. This necessitates mandatory AI training for all engineering faculty, the establishment of sabbatical programs for faculty to gain up-to-date industry experience, and incentives for faculty to pursue advanced degrees in AI.

Furthermore, the government should leverage and expand its existing digital public infrastructure (such as UPI and Aadhaar) to build a rich ecosystem of India-specific datasets for AI training. This effort should encompass anonymized transaction data from digital payment systems, critical government data on agriculture, health, and education, and comprehensive multilingual datasets for Indian language Natural Language Processing (NLP) applications.

9.2 Institutional Reforms for Engineering Education

Educational institutions must undertake reforms focused on three key areas: modernizing curricula, investing in faculty capability, and strengthening ties with industry.

Industry-academia collaboration should be enhanced through several initiatives: structuring internship programs that immerse students in real-world AI projects, hosting guest lectures and workshops led by industry experts, and launching joint research initiatives to solve relevant industry challenges.

Colleges also need to transition towards a project-based learning model. Students should be actively engaged in building, testing, and refining actual AI applications throughout their degree programs. This shift from a purely theoretical focus to an application-oriented pedagogy is vital for producing industry-ready AI professionals.

9.3 A Student’s Roadmap for Future-Proofing Skills

For students like Dhruba Saha, success in the AI-driven economy demands a proactive and continuous approach to learning. Students must develop a comprehensive skillset, encompassing both technical foundations and essential soft skills.

This involves mastering the fundamentals of mathematics and statistics, achieving proficiency in contemporary AI frameworks and tools, and cultivating soft skills such as critical thinking, collaboration, and communication. Students should actively seek out research projects and internships to gain practical, real-world experience. By building a diverse portfolio of projects and committing to lifelong learning, students can effectively position themselves for success.

9.4 Final Synthesis and Conclusion

Indian engineering students face significant, interconnected challenges in achieving proficiency in artificial intelligence. These constraints are evident across multiple dimensions:

- **Technical and Soft Skills:** Gaps in core skills like mathematics, algorithms, domain-specific AI knowledge, learning agility, critical thinking, and communication.
- **Educational Factors:** Hindrances such as outdated curricula and insufficient AI knowledge among faculty.
- **Infrastructure:** Limitations in access to necessary resources, including GPU compute power and modern software licenses.
- **Systemic Issues:** Broader challenges like brain drain, scarcity of high-quality research opportunities, and lack of adequate data.

Crucially, these limitations are not insurmountable. India holds distinct advantages, including a large and expanding pool of STEM talent, a dynamic startup environment, strong government support (exemplified by the IndiaAI Mission), and a growing consensus on the need for educational reform.

Recent progress, such as AICTE initiatives to integrate AI into engineering curricula, the expansion of GPU infrastructure through the IndiaAI Compute Portal, and increasing industry-academia collaboration, demonstrates that positive change is achievable. The way forward requires synchronized action from all key stakeholders: the government, educational institutions, the industry, and the students themselves.

The imperative is clear. India's future competitiveness in the global AI landscape hinges on its capacity to develop a workforce that can not only utilize AI tools but also lead, innovate, and drive new AI development. By implementing the strategic, coordinated actions outlined in this report, India can revitalize its engineering education system and secure its position as a global leader in artificial intelligence.
